### Abstract

Our open-source code PetIBM—an immersed boundary method with a fully discrete projection formulation—was written to take advantage of the PETSc library for solving the Poisson system. We have now added the capacity to accelerate the time to solution on CUDA-capable GPU devices using the Nvidia library AmgX. Our application of interest is the three-dimensional flow around a flying-snake, to reveal the lift-enhancement mechanisms used by this unconventional glider.

Keywords: Immersed Boundary Method, PETSc, AmgX, flying snake

## 1. PetIBM and AmgXWrapper

We have developed PetIBM¹ that implements using the PETSc² library, an immersed-boundary method (IBM) [?] in which the fully discrete algebraic system is solved via a projection method based on an approximate block-LU decomposition. The data structures and routines provided by the PETSc library allowed us to rapidly develop a software that runs on distributed-memory architectures.

As expected with the projection method, the iterative Poisson solver is the bottleneck in our simulations. This is even worse for the IBM we use where

the modified Poisson operator becomes larger and possesses more off-diagonal entries. To overcome this challenge, we use the Nvidia-library AmgX<sup>3</sup> to solve the iterative system on multiple CUDA-capable GPU devices. We have developed an AmgX wrapper<sup>4</sup> that provides the interface with the PETSc library and incorporated it in PetIBM. Past two-dimensional simulations with PetIBM showed a 21 times application speed-up in runtime from using our AmgX wrapper on one GPU node compared to using PETsc on a CPU node (see Figure ??).

The full codes, PetIBM and AmgXWrapper, are open-source, released under MIT license, and version-controlled on GitHub.

# 2. Flying snakes to the cloud

We aim to study the aerodynamics of the *Chrysopelea paradisi*, a species of snake with the amazing capability to glide through the air. Previous experimental work [?] and two-dimensional simulations [?] reported enhanced lift force on a snake gliding at a particular angle of attack of 35°. Using PetIBM and AmgXWrapper, we now intend to understand the three-dimensional wake structures responsible for high gliding performances of the paradise tree snake.

Finally, we decided to use the public cloud Microsoft Azure to run our simulations so that we could compare the performances with our University HPC cluster.
